The potential benefits of transporting CO₂ in shared infrastructure

Economy of scale

CO₂ sources are decentralised, and long distance and multimodal transport chains are needed. Increasing the transport capacity reduces the costs of logistics.

Balancing of seasonally variable capture

Entry of smaller capture facilities

Opportunity to reach sufficient economies of scale, while also encouraging CCUS participation due to sharing of costs and risks.

Efficient logistics for CO₂ markets

EU's [Industrial carbon management strategy](#) aims to develop needed regulatory frameworks, market design and infrastructure planning, establish standards, and assess the use of existing infrastructure for CO₂ transport.

Outlook of CO₂ logistics in Finland for CCUS

Summary

The report summarises the results from our study on potential development of CO₂ logistics in Finland, for the purposes of carbon capture, utilization, and storage (CCUS). The study provides an outlook on Finland's industrial carbon dioxide emission sources, evaluates potential CO₂ hub locations, export terminals and inland intermediate storage facilities, and assesses transport costs and required investments for CO₂ logistics infrastructure.

The examined industrial facilities emitted a total of 40 MCO₂/year in 2022, of which 30.1 MCO₂/year is biogenic. Nine potential regional CO₂ hubs were identified and used to create three scenarios for future CO₂ logistics system in Finland. The scenarios show how 25.2 MCO₂/year (of which 21.6 M is biogenic) could be collected for utilization or geological storage from the hubs. Additionally, we investigated two alternative transline scenarios with higher capacities, allowing to transport CO₂ between the hubs while also providing greater coverage of the transport network to regions outside the larger CO₂ hubs.

Assuming rail transport of CO₂ for facilities connected by the railway network, the weighted average transport cost in the hubs was between 20-59 €/tCO₂. The cost includes initial compression or liquefaction and buffer storage at the destination for both utilization and permanent storage options. Capital costs in the scenarios were between 0.7-4.7 €/tCO₂. Required investment was the lowest in the utilization-heavy scenario as it also has the lowest transport demands of all the scenarios. Highest investments were required in the scenario with an emphasis on geological storage where a significant amount of CO₂ is transported to coastal locations for further shipping to storage sites. The baseline scenario examined transport of 22.2-38.1 MCO₂/year (of which 20.1-25.8 M is biogenic) to utilization sites and hubs in four coastal locations. The total weighted average cost of transport was between 40-60 €/tCO₂ in the assessed boundaries.

Utilising the existing railway infrastructure for CO₂ transport is economically sensible based on the results. Comparison of the assessed transport modes shows that pipelines are less expensive option to transport CO₂ over shorter distances when capacity is high enough. If capacity becomes under 1 MCO₂/year, pipelines start to lose their advantage over rail and road transportation.

Bio-CO₂ Use and Removal

Vantaan Energia

06.05.2025

DRAFT

Vantaa Energy CCS project will capture ~650 ktpa of CO₂ emissions to future-proof its current Waste-to-Energy plant

Decarbonizing is key for European Waste-to-Energy plants to be competitive long term

CCS is Vantaa Energy's best option to decarbonize – sufficiently mature technology with state/EU funding options

The CO₂ will be transported by a **6 km pipeline to Vuosaari port**, liquefied and shipped for storage in the North Sea

Planned construction start in 2027 and **commissioning in 2030**

VECCS is an ideal project to unlock a scaled CCS value chain in Finland's South-East emitter cluster

/ ILLUSTRATIVE

Emitters are scattered, with no value chain infra.

VECCS builds first-of-kind CO₂ port, enabling CCS value chain
